FORGE Version 0 1 Beta Update Log

Implementation summary and handoff notes

FORGE v0.1 Beta is a complete local Next.js prototype for gamified productivity and skill development. The beta implements the planned loop from campaign selection through focused work, quest completion, XP gain, and dashboard progress. It uses mock data only and keeps the codebase ready for future persistence, accounts, AI generation, and native mobile work.

Current Scope

Route	Purpose
/	Product entry page with the beta concept and campaign entry points.
/dashboard	Shows level, XP progress, streak, active campaign, next quest, and quest board.
/campaign	Shows the Python Developer campaign, available quests, progress, and the upcoming boss quest.
/focus	Runs a quest-specific focus session with a countdown timer and a completion action.
/complete	Shows quest completion, XP earned, and links back to progress or the campaign.

Core Product Loop

A user opens the dashboard, selects a quest, and enters a focus session. Completing the session records the quest in the in-memory beta state, adds the quest reward to XP, and presents the completion screen. Returning to the dashboard shows the updated XP total, cleared quest count, campaign progress, and completed quest state.

Reusable Components

Component	Role
XPBar	Displays current XP against the next level target.
QuestCard	Presents difficulty, focus duration, XP reward, completion state, and start action.
CampaignCard	Shows the active campaign, completion progress, and campaign entry point.
StatCard	Displays streak, focus time, and cleared quest statistics.
FocusTimer	Runs the focus countdown with pause, reset, and completion behavior.

Mock Data and Boundaries

The beta includes a Python Developer campaign with three available practice quests and one upcoming boss quest. Mock data defines the user profile, level, XP, streak, campaign metadata, quest difficulty, reward, duration, and focus prompt. Progress exists only for the current browser session. The project does not include authentication, a database, AI APIs, payments, social features, leaderboards, or screen-time blocking.

Project Structure

Location	Contents
app	App Router pages, root layout, and global styling.
components	Reusable UI cards, navigation, timer, XP bar, and in-memory progress provider.
lib	Mock user, campaign, quest data, and shared TypeScript types.

Verification

The project passed ESLint and a production Next.js build. All requested routes are statically generated successfully. The implementation uses standard Next.js, React, TypeScript, and Tailwind packages with no additional runtime dependencies.

Recommended Next Work

Future work can replace the in-memory provider with persistent user progress, add campaign creation, and connect account or AI features without changing the current route and component boundaries. Those features are intentionally outside the v0.1 Beta scope.
